ADC0844/ADC0848
8-Bit µP Compatible A/D Converters with Multiplexer Options

General Description
The ADC0844 and ADC0848 are CMOS 8-bit successive approximation A/D converters with versatile analog input multiplexers. The 4-channel or 8-channel multiplexers can be software configured for single-ended, differential or pseudo-differential modes of operation.

The differential mode provides low frequency input common mode rejection and allows offsetting the analog range of the converter. In addition, the A/D’s reference can be adjusted enabling the conversion of reduced analog ranges with 8-bit resolution.

The A/Ds are designed to operate from the control bus of a wide variety of microprocessors. TRI-STATE output latches that directly drive the data bus permit the A/Ds to be configured as memory locations or I/O devices to the microprocessor with no interface logic necessary.

Features
- Easy interface to all microprocessors
- Operates ratiometrically or with 5 V<sub>DC</sub> voltage reference
- No zero or full-scale adjust required
- 4-channel or 8-channel multiplexer with address logic
- Internal clock
- 0V to 5V input range with single 5V power supply
- 0.3” standard width 20-pin or 24-pin DIP
- 28 Pin Molded Chip Carrier Package

Key Specifications
- Resolution 8 Bits
- Total Unadjusted Error ±½ LSB and ± 1 LSB
- Single Supply 5 V<sub>DC</sub>
- Low Power 15 mW
- Conversion Time 40 µs

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating conditions.

**Note 2:** All voltages are measured with respect to the ground pins.

**Note 3:** When the input voltage ($V_{IN}$) at any pin exceeds the power supply rails ($V_{IN} < V^\prime$ or $V_{IN} > V^\prime$) the absolute value of the current at that pin should be limited to 5 mA or less. The 20 mA package input current limits the number of pins that can exceed the power supply boundaries with a 5 mA current limit to four.

**Note 4:** Human body model, 100 pF discharged through a 1.5 kΩ resistor.

**Note 5:** Typical limits are tested and guaranteed to National’s AOQL (Average Outgoing Quality Level).

**Note 6:** Design limits are guaranteed by not 100% tested. These limits are not used to calculate outgoing quality levels.

**Note 7:** All limits are not used to calculate outgoing quality levels.

**Note 8:** Total unadjusted error includes offset, full-scale, linearity, and multiplexer error.

**Note 9:** For $V_{IN} (<) > V_{IN}(>)$ the digital output code will be 0000 0000. Two on-chip diodes are tied to each analog input, which will forward-conduct for analog input voltages one diode drop below ground or one diode drop greater than $V_{CC}$ supply. Be careful during testing at low $V_{CC}$ levels (4.5V), as high level input voltages can cause this input diode to conduct, especially at elevated temperatures, and cause errors to analog inputs near full-scale. The spec allows 50 mV forward bias of either diode. This means that as long as the analog $V_{IN}$ does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 to 5 $V_{DC}$ input voltage range will therefore require a minimum supply voltage of 4.950 $V_{DC}$ over temperature variations, initial tolerance and loading.

**Note 10:** Off channel leakage current is measured after the channel selection.

**Note 11:** The temperature coefficient is 0.3%/°C.

Programming New Channel Configuration and Starting a Conversion

Using the Previously Selected Channel Configuration and Starting a Conversion

Note 12: Read strobe must occur at least 600 ns after the assertion of interrupt to guarantee reset of INTR.

Note 13: MA stands for MUX address.
Functional Description

The ADC0844 and ADC0848 contain a 4-channel and 8-channel analog input multiplexer (MUX) respectively. Each MUX can be configured into one of three modes of operation: differential, pseudo-differential, and single ended. These modes are discussed in the Applications Information Section. The specific mode is selected by loading the MUX address latch with the proper address (see Table 1 and Table 2). Inputs to the MUX address latch (MA0-MA4) are common with data bus lines (DB0-DB4) and are enabled when the RD line is high. A conversion is initiated via the CS and WR lines. If the data from a previous conversion is not read, the INTR line will be low. The falling edge of WR will reset the INTR line high and ready the A/D for a conversion cycle. The rising edge of WR, with RD high, strobes the data on the MA0/DB0-MA4/DB4 inputs into the MUX address latch to select a new input configuration and start a conversion. If the RD line is held low during the entire low period of WR the previous MUX configuration is retained, and the data of the previous conversion is the output on lines DB0-DB7. After the conversion cycle (tC ≤ 40 µs), which is set by the internal clock frequency, the digital data is transferred to the output latch and the INTR is asserted low. Taking CS and RD low resets INTR output high and outputs the conversion result on the data lines (DB0-DB7).

Applications Information

1.0 MULTIPLEXER CONFIGURATION

The design of these converters utilizes a sampled-data comparator structure which allows a differential analog input to be converted by a successive approximation routine. The actual voltage converted is always the difference between an assigned “+” input terminal and a “−” input terminal. The polarity of each input terminal of the pair being converted indicates which line the converter expects to be the most positive. If the assigned “+” input is less than the “−” input the converter responds with an all zeros output code.

A unique input multiplexing scheme has been utilized to provide multiple analog channels. The input channels can be software configured into three modes: differential, single ended, or pseudo-differential. Figure 1 shows the three modes using the 4-channel MUX ADC0844. The eight inputs of the ADC0848 can also be configured in any of the three modes. In the differential mode, the ADC0844 channel inputs are grouped in pairs, CH1 with CH2 and CH3 with CH4. The polarity assignment of each channel in the pair is interchangeable. The single-ended mode has CH1–CH4 assigned as the positive input with the negative input being the analog ground (AGND) of the device. Finally, in the pseudo-differential mode CH1–CH3 are positive inputs referenced to CH4 which is now a pseudo-ground. This pseudo-ground input can be set to any potential within the input common-mode range of the converter. This type of input flexibility. One converter package can now handle ground referenced inputs and true differential inputs as well as signals with some arbitrary reference voltage.

The analog input voltages for each channel can range from 50 mV below ground to 50 mV above VCC (typically 5V) without degrading conversion accuracy.

Applications Information (Continued)

2.0 REFERENCE CONSIDERATIONS

The voltage applied to the reference input of these converters defines the voltage span of the analog input (the difference between \( V_{\text{IN(MAX)}} \) and \( V_{\text{IN(MIN)}} \)) over which the 256 possible output codes apply. The devices can be used in either ratiometric applications or in systems requiring absolute accuracy. The reference pin must be connected to a voltage source capable of driving the minimum reference input resistance of 1.1 k\( \Omega \). This pin is the top of a resistor divider string used for the successive approximation conversion.

In a ratiometric system (Figure 2a), the analog input voltage is proportional to the voltage used for the A/D reference. This voltage is typically the system power supply, so the \( V_{\text{REF}} \) pin can be tied to \( V_{\text{CC}} \). This technique relaxes the stability requirements of the system reference as the analog input and A/D reference move together maintaining the same output code for a given input condition.

For absolute accuracy (Figure 2b), where the analog input varies between very specific voltage limits, the reference pin can be biased with a time and temperature stable voltage source. The LM385 and LM336 reference diodes are good low current devices to use with these converters.

The maximum value of the reference is limited to the \( V_{\text{CC}} \) supply voltage. The minimum value, however, can be quite small (see Typical Performance Characteristics) to allow direct conversions of transducer outputs providing less than a 5V output span. Particular care must be taken with regard to noise pickup, circuit layout and system error voltage sources when operating with a reduced span due to the increased sensitivity of the converter (1 LSB equals \( V_{\text{REF}}/256 \)).

3.0 THE ANALOG INPUTS

3.1 Analog Differential Voltage Inputs and Common-Mode Rejection

The differential input of these converters actually reduces the effects of common-mode input noise, a signal common to both selected “+” and “−” inputs for a conversion (60 Hz is most typical). The time interval between sampling the “+” input and then the “−” inputs is \( \frac{1}{2} \) of a clock period. The change in the common-mode voltage during this short time interval can cause conversion errors. For a sinusoidal common-mode signal this error is:

\[
V_{\text{ERROR(MAX)}} = V_{\text{peak}} \left(2\pi f_{\text{CM}}\right) \times 0.5 \times \frac{t_{\text{C}}}{8}
\]

where \( f_{\text{CM}} \) is the frequency of the common-mode signal, \( V_{\text{peak}} \) is its peak voltage value and \( t_{\text{C}} \) is the conversion time. For a 60 Hz common-mode signal to generate a \( \frac{1}{4} \) LSB error (\( \approx 5 \text{ mV} \)) with the converter running at 40 \( \mu \text{S} \), its peak value would have to be 5.43V. This large a common-mode signal is much greater than that generally found in a well designed data acquisition system.

#### 3.2 Input Current

Due to the sampling nature of the analog inputs, short duration spikes of current enter the “+” input and exit the “−” input at the clock edges during the actual conversion. These currents decay rapidly and do not cause errors as the internal comparator is strobed at the end of a clock period. Bypass capacitors at the inputs will average these currents and cause an effective DC current to flow through the output resistance of the analog signal source. Bypass capacitors should not be used if the source resistance is greater than 1 kΩ.

#### 3.3 Input Source Resistance

The limitation of the input source resistance due to the DC leakage currents of the input multiplexer is important. A worst-case leakage current of ±1 µA over temperature will create a 1 mV input error with a 1 kΩ source resistance. An op amp RC active low pass filter can provide both impedance buffering and noise filtering should a high impedance signal source be required.

#### 4.0 OPTIONAL ADJUSTMENTS

##### 4.1 Zero Error

The zero of the A/D does not require adjustment. If the minimum analog input voltage value, $V_{IN(MIN)}$, is not ground, a zero offset can be done. The converter can be made to output 0000 0000 digital code for this minimum input voltage by biasing any $V_{IN}$ (−) input at this $V_{IN(MIN)}$ value. This is useful for either differential or pseudo-differential modes of input channel configuration.

The zero error of the A/D converter relates to the location of the first riser of the transfer function and can be measured by grounding the $V^−$ input and applying a small magnitude positive voltage to the $V^+$ input. Zero error is the difference between actual DC input voltage which is necessary to just cause an output digital code transition from 0000 0000 to 0000 0001 and the ideal $\frac{1}{2}$ LSB value ($\frac{1}{2}$ LSB = 9.8 mV for $V_{REF}=5.000$ VDC).

##### 4.2 Full-Scale

The full-scale adjustment can be made by applying a differential input voltage which is $1 \frac{1}{2}$ LSB down from the desired analog full-scale voltage range and then adjusting the magnitude of the $V_{REF}$ input for a digital output code changing from 1111 1110 to 1111 1111.

##### 4.3 Adjusting for an Arbitrary Analog Input Voltage Range

If the analog zero voltage of the A/D is shifted away from ground (for example, to accommodate an analog input signal which does not go to ground), this new zero reference should be properly adjusted first. A $V_{IN}$ (+) voltage which equals this desired zero reference plus $\frac{1}{2}$ LSB (where the LSB is calculated for the desired analog span, 1 LSB = analog span/256) is applied to selected “+” input and the
zero reference voltage at the corresponding "−" input should then be adjusted to just obtain the 00\text{HEX} to 01\text{HEX} code transition.

The full-scale adjustment should be made [with the proper $V_{\text{IN}}$ (−) voltage applied] by forcing a voltage to the $V_{\text{IN}}$ (+) input which is given by:

$$V_{\text{IN}} (\pm) \text{ fs adj} = V_{\text{MAX}} - 1.5 \left( \frac{V_{\text{MAX}} - V_{\text{MIN}}}{256} \right)$$

where $V_{\text{MAX}}$=the high end of the analog input range and $V_{\text{MIN}}$=the low end (the offset zero) of the analog range. (Both are ground referenced.)

The $V_{\text{REF}}$ (or $V_{\text{CC}}$) voltage is then adjusted to provide a code change from $\text{FE}_{\text{HEX}}$ to $\text{FF}_{\text{HEX}}$. This completes the adjustment procedure.

For an example see the Zero-Shift and Span Adjust circuit below.
Differential Voltage Input 9-Bit A/D

Span Adjust (0V ≤ V_{IN} ≤ 3V)

Protecting the Input

Diodes are 1N914

DO=all 0s if $V_{IN(+)} < V_{IN(-)}$

Operating with Automotive Ratiometric Transducers

$V_{IN(-)} = 0.15\ V_{CC}$
$15\% \text{ of } V_{CC} \leq V_{XDR} \leq 85\% \text{ of } V_{CC}$
Notes: DUT pin numbers in parentheses are for ADC0844, others are for ADC0848.

Start a Conversion without Updating the Channel Configuration

- CS • WR will update the channel configuration and start a conversion.
- CS • RD will read the conversion data and start a new conversion without updating the channel configuration.

Waiting for the end of this conversion is not necessary. A CS • WR can immediately follow the CS • RD.

END

Note 14: This routine sequentially programs the MUX data latch in the signal-ended mode. For CH1-CH8 a conversion is started, then a 50 µs wait for the A/D to complete a conversion and the data is stored at address ADDTA for CH1, ADDTA + 1 for CH2, etc.

LIFE SUPPORT POLICY

NATIONAL’S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.

2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied and National reserves the right at any time without notice to change said circuitry and specifications.
